

case	steady-state result	design implication
$R = 0, N = 1/s$	$e_{ssn} = \frac{1}{K_1 K_3}$	increase K_1 and K_3 to reduce load disturbance effect
$N = 0, R = 1/s$ input-side error	$e_{ss} = 0$	no input-side steady-state error
$N = 0, R = 1/s$ output-side error	$e_{ssr} = 1 - \frac{1}{K_3}$	$K_3 = 1$ makes output-side steady-state error zero
