

key point	how to compute	what it corrects
breakaway point	$\sum \frac{1}{d-p_i} = \sum \frac{1}{d-z_j}$	where branches leave the real axis
departure angle	pole-centered angle balance	initial tangent near complex poles
arrival angle	zero-centered angle balance	final tangent near complex zeros
imaginary-axis crossing	set $s = j\omega$ and solve real/imag parts	stability boundary and critical gain
